The turbine turns a shaft which rotates a series of magnets past copper coils and a generator to produce electricity. The process produces clean renewable energy.

As the turbine blades rotate, they draw more air into the compressor, sustaining a continuous cycle. This rotation powers the generator, converting mechanical ...

The cross-flow turbine allows water to flow through the blades twice. On the first pass, water flows from outside of the blades to the inside; the second pass goes from the inside back out.

The first stage vanes slow the air down and direct it towards the second stage compressor rotor blades, and so on through the compressor rotor stages (each stage is one rotating stage and one stationary ...

The high-speed shaft drives the generator, which uses copper windings to turn through a magnetic field. This action produces renewable energy in the form of alternating current (AC).

The working principle of a turbine generator follows this simple sequence: Energy Input: A fluid (such as steam, gas, or water) is directed at ...

Wind Tunnel Energy Generator: Fueling Optimism for Clean Energy It captures wind through an above-ground portal, channels it through a duct to increase its speed, and then uses the kinetic energy to ...

Impulse Turbines: This type, which includes the Pelton wheel, uses the velocity of the water to move the blades of the turbine. These are typically ...

The blades of a turbine are twisted as they extend from the rotor to the blade tip. This increases the force exerted near the tip, as the tip moves ...
