From the major planets in our Solar System to the very Sun itself, the sphere is the most common shape of celestial bodies, but why are the planets ...

This is a list of most likely gravitationally rounded objects (GRO) of the Solar System, which are objects that have a rounded, ellipsoidal shape due to their own gravity (but are not necessarily in hydrostatic equilibrium). Apart from the Sun itself, these objects qualify as planets according to common geophysical definitions of that term. The radii of these objects range over three orders of magnitude, from planetary-mass objects like dwarf planets and some moons to the planets and the Sun. This list does not include small Solar System bodies

The orbits of the planets in our solar system (and the vast majority of planetary objects in space) are not perfectly circular. Planets have orbital ...

In general, the orbits of planets and other astronomical bodies are not perfectly circular. They're elliptical. However, the motions of most planets and satellites in our solar system are nearly circular. ...

Mercury and Venus are the roundest of all. They are nearly perfect spheres, like marbles. But some planets aren't quite so perfectly round. Saturn ...

In our solar system, with the exception of Pluto all planets follow a relatively circular orbit around the Sun, at the same inclination. They also all ...

Move the sun, earth, moon and space station to see how it affects their gravitational forces and orbital paths. Visualize the sizes and distances between different ...

Many maps of the solar system make it look as though everything ...

The Sun and all eight planets of the solar system are round. Why? The gravitational force of a planet's mass pulls all of its material toward the center, smoothing out ...
